Chapter Overview

- **Broadcast Networks**
  - All information sent to all users
  - No routing
  - Shared media
  - Radio
    - Cellular telephony
    - Wireless LANs
  - Copper & Optical
    - Ethernet LANs
    - Cable Modem Access

- **Medium Access Control**
  - To coordinate access to shared medium
  - Data link layer since direct transfer of frames

- **Local Area Networks**
  - High-speed, low-cost communications between co-located computers
  - Typically based on broadcast networks
  - Simple & cheap
  - Limited number of users

Chapter 6
Medium Access Control Protocols and Local Area Networks

Multiple Access Communications
Multiple Access Communications

- Shared media basis for broadcast networks
  - Inexpensive: radio over air; copper or coaxial cable
  - $M$ users communicate by broadcasting into medium
- Key issue: How to share the medium?
Approaches to Media Sharing

Medium sharing techniques

- Static channelization
- Dynamic medium access control

Scheduling

- Polling: take turns
- Request for slot in transmission schedule
- Token ring
- Wireless LANs

Random access

- Loose coordination
- Send, wait, retry if necessary
- Aloha
- Ethernet

- Partition medium
- Dedicated allocation to users
- Satellite transmission
- Cellular Telephone
Channelization: Satellite

Satellite Channel

uplink $f_{in}$

downlink $f_{out}$
Channelization: Cellular

uplink $f_1$ ; downlink $f_2$

uplink $f_3$ ; downlink $f_4$
Scheduling: Polling

- **Host computer**
- **Poll 1**
- **Poll 2**
- **Stations**: 1, 2, 3
- **Inbound line**
- **Outbound line**
- **Data from 1**
- **Data from 2**
- **Data to M**
Scheduling: Token-Passing

Ring networks

Station that holds token transmits into ring
Random Access

Multitapped Bus

Transmit when ready

Transmissions can occur; need retransmission strategy
Wireless LAN

AdHoc: station-to-station
Infrastructure: stations to base station
Random access & polling
Selecting a Medium Access Control

- Applications
  - What type of traffic?
  - Voice streams? Steady traffic, low delay/jitter
  - Data? Short messages? Web page downloads?
  - Enterprise or Consumer market? Reliability, cost

- Scale
  - How much traffic can be carried?
  - How many users can be supported?

- Current Examples:
  - Design MAC to provide wireless DSL-equivalent access to rural communities
  - Design MAC to provide Wireless-LAN-equivalent access to mobile users (user in car travelling at 130 km/hr)
Delay-Bandwidth Product

- *Delay-bandwidth* product key parameter
  - Coordination in sharing medium involves using bandwidth (explicitly or implicitly)
  - Difficulty of coordination commensurate with delay-bandwidth product

- Simple two-station example
  - Station with frame to send listens to medium and transmits if medium found idle
  - Station monitors medium to detect collision
  - If collision occurs, station that begin transmitting earlier retransmits (propagation time is known)
Two-Station MAC Example

Two stations are trying to share a common medium

A transmits at \( t = 0 \)

Distance \( d \) meters

\[ t_{\text{prop}} = \frac{d}{\nu} \text{ seconds} \]

B does not transmit before \( t = t_{\text{prop}} \) & A captures channel

Case 1

A detects collision at \( t = 2 \ t_{\text{prop}} \)

B transmits before \( t = t_{\text{prop}} \) and detects collision soon thereafter

Case 2
Efficiency of Two-Station Example

- Each frame transmission requires $2t_{prop}$ of quiet time
  - Station B needs to be quiet $t_{prop}$ before and after time when Station A transmits
  - $R$ transmission bit rate
  - $L$ bits/frame

$$Efficiency = \rho_{max} = \frac{L}{L + 2t_{prop}R} = \frac{1}{1 + 2t_{prop}R / L} = \frac{1}{1 + 2a}$$

$$MaxThroughput = R_{eff} = \frac{L}{L / R + 2t_{prop}} = \frac{1}{1 + 2a} R \text{ bits/second}$$

$\rho_{max}$
$R_{eff}$

- $a = \frac{t_{prop}}{L / R}$
  - Propagation delay
  - Time to transmit a frame

Normalized Delay-Bandwidth Product
Typical MAC Efficiencies

Two-Station Example:

\[
\text{Efficiency} = \frac{1}{1 + 2a}
\]

CSMA-CD (Ethernet) protocol:

\[
\text{Efficiency} = \frac{1}{1 + 6.44a}
\]

Token-ring network

\[
\text{Efficiency} = \frac{1}{1 + a'}
\]

- If \(a << 1\), then efficiency close to 100%
- As \(a\) approaches 1, the efficiency becomes low

\(a' = \) latency of the ring (bits)/average frame length
Typical Delay-Bandwidth Products

- Max size Ethernet frame: 1500 bytes = 12000 bits
- Long and/or fat pipes give large \( a \)
MAC protocol features

- Delay-bandwidth product
- Efficiency
- Transfer delay
- Fairness
- Reliability
- Capability to carry different types of traffic
- Quality of service
- Cost
MAC Delay Performance

- **Frame transfer delay**
  - From first bit of frame arrives at source MAC
  - To last bit of frame delivered at destination MAC

- **Throughput**
  - Actual transfer rate through the shared medium
  - Measured in frames/sec or bits/sec

- **Parameters**
  - $R$ bits/sec & $L$ bits/frame
  - $X = \frac{L}{R}$ seconds/frame
  - $\lambda$ frames/second average arrival rate
  - Load $\rho = \lambda \cdot X$, rate at which “work” arrives
  - Maximum throughput (@100% efficiency): $\frac{R}{L}$ fr/sec
Normalized Delay versus Load

$E[T]/X$

$E[T] = \text{average frame transfer delay}$

$X = \text{average frame transmission time}$

- At low arrival rate, only frame transmission time
- At high arrival rates, increasingly longer waits to access channel
- Max efficiency typically less than 100%
Dependence on $R_{t\text{prop}}/L$

$E[T]/X$

$a' > a$

Transfer Delay

$\rho_{\text{max}}$

Load

$\rho$

$\rho_{\text{max}}$

Chapter 6
Medium Access Control Protocols and Local Area Networks

Random Access
ALOHA

- Wireless link to provide data transfer between main campus & remote campuses of University of Hawaii
- Simplest solution: just do it
  - A station transmits whenever it has data to transmit
  - If more than one frames are transmitted, they interfere with each other (collide) and are lost
  - If ACK not received within timeout, then a station picks random backoff time (to avoid repeated collision)
  - Station retransmits frame after backoff time

\[
\begin{align*}
&\text{First transmission} \\
&t_0-X \quad t_0 \quad t_0+X \\
&t_0+X + 2t_{\text{prop}} \quad t_0+X+2t_{\text{prop}} + B \\
&\text{Backoff period } B \\
&\text{Vulnerable period} \\
&\text{Time-out}
\end{align*}
\]
ALOHA Model

- Definitions and assumptions
  - $X$: frame transmission time (assume constant)
  - $S$: throughput (average # successful frame transmissions per $X$ seconds)
  - $G$: load (average # transmission attempts per $X$ sec.)
  - $P_{success}$: probability a frame transmission is successful

\[
S = GP_{success}
\]

- Any transmission that begins during vulnerable period leads to collision
- Success if no arrivals during $2X$ seconds
**Abramson’s Assumption**

- *What is probability of no arrivals in vulnerable period?*
- Abramson assumption: Effect of backoff algorithm is that frame arrivals are equally likely to occur at any time interval
- $G$ is avg. # arrivals per $X$ seconds
- Divide $X$ into $n$ intervals of duration $\Delta = X/n$
- $p = \text{probability of arrival in } \Delta \text{ interval, then}$
  
  $G = np$  \quad \text{since there are } n \text{ intervals in } X \text{ seconds}

$$P_{\text{success}} = P[0 \text{ arrivals in } 2X \text{ seconds}] =$$

$$= P[0 \text{ arrivals in } 2n \text{ intervals}]$$

$$= (1 - p)^{2n} = (1 - \frac{G}{n})^{2n} \rightarrow e^{-2G} \quad \text{as } n \rightarrow \infty$$
Throughput of ALOHA

\[ S = G P_{success} = Ge^{-2G} \]

- Collisions are means for coordinating access
- Max throughput is \( \rho_{max} = \frac{1}{2e} \) (18.4%)
- Bimodal behavior:
  - Small G, S\(\approx G\)
  - Large G, S\(\downarrow 0\)
- Collisions can snowball and drop throughput to zero
Slotted ALOHA

- Time is slotted in X seconds slots
- Stations synchronized to frame times
- Stations transmit frames in first slot after frame arrival
- Backoff intervals in multiples of slots

Only frames that arrive during prior X seconds collide
Throughput of Slotted ALOHA

\[ S = GP_{\text{success}} = GP[\text{no arrivals in X seconds}] \]
\[ = GP[\text{no arrivals in n intervals}] \]
\[ = G(1 - p)^n = G\left(1 - \frac{G}{n}\right)^n \rightarrow Ge^{-G} \]
Application of Slotted Aloha

- Reservation protocol allows a large number of stations with infrequent traffic to reserve slots to transmit their frames in future cycles.
- Each cycle has mini-slots allocated for making reservations.
- Stations use slotted Aloha during mini-slots to request slots.
Carrier Sensing Multiple Access (CSMA)

- A station senses the channel before it starts transmission
  - If busy, either wait or schedule backoff (different options)
  - If idle, start transmission
  - Vulnerable period is reduced to $t_{prop}$ (due to channel capture effect)
  - When collisions occur they involve entire frame transmission times
  - If $t_{prop} > X$ (or if $a > 1$), no gain compared to ALOHA or slotted ALOHA

Station A begins transmission at $t = 0$

Station A captures channel at $t = t_{prop}$
CSMA Options

- Transmitter behavior when busy channel is sensed
  - 1-persistent CSMA (most greedy)
    - Start transmission as soon as the channel becomes idle
    - Low delay and low efficiency
  - Non-persistent CSMA (least greedy)
    - Wait a backoff period, then sense carrier again
    - High delay and high efficiency
  - p-persistent CSMA (adjustable greedy)
    - Wait till channel becomes idle, transmit with prob. $p$; or wait one mini-slot time & re-sense with probability $1-p$
    - Delay and efficiency can be balanced

![Sensing Diagram]
$1$-Persistent CSMA Throughput

- Better than Aloha & slotted Aloha for small $a$
- Worse than Aloha for $a > 1$
Non-Persistent CSMA Throughput

- Higher maximum throughput than 1-persistent for small $a$
- Worse than Aloha for $a > 1$
CSMA with Collision Detection (CSMA/CD)

- Monitor for collisions & abort transmission
  - Stations with frames to send, first do carrier sensing
  - After beginning transmissions, stations continue listening to the medium to detect collisions
  - If collisions detected, all stations involved stop transmission, reschedule random backoff times, and try again at scheduled times
- In CSMA collisions result in wastage of X seconds spent transmitting an entire frame
- CSMA-CD reduces wastage to time to detect collision and abort transmission
CSMA/CD reaction time

It takes $2t_{prop}$ to find out if channel has been captured
CSMA-CD Model

- Assumptions
  - Collisions can be detected and resolved in $2t_{prop}$
  - Time slotted in $2t_{prop}$ slots during contention periods
  - Assume $n$ busy stations, and each may transmit with probability $p$ in each contention time slot
  - Once the contention period is over (a station successfully occupies the channel), it takes $X$ seconds for a frame to be transmitted
  - It takes $t_{prop}$ before the next contention period starts.
Contestation Resolution

- How long does it take to resolve contention?
- Contestation is resolved (“success”) if exactly 1 station transmits in a slot:

\[ P_{success} = np(1 - p)^{n-1} \]

- By taking derivative of \( P_{success} \) we find max occurs at \( p = 1/n \)

\[ P_{max}^{success} = n \left(1 - \frac{1}{n}\right)^{n-1} = \left(1 - \frac{1}{n}\right)^{n-1} \rightarrow \frac{1}{e} \]

- On average, \( 1/P_{max} = e = 2.718 \) time slots to resolve contention

Average Contestation Period = \( 2t_{prop} e \) seconds
**CSMA/CD Throughput**

- At maximum throughput, systems alternates between contention periods and frame transmission times

\[
\rho_{\text{max}} = \frac{X}{X + t_{\text{prop}} + 2et_{\text{prop}}} = \frac{1}{1 + (2e + 1)a} = \frac{1}{1 + (2e + 1)Rd / \nu L}
\]

- where:
  - \( R \) bits/sec, \( L \) bits/frame, \( X = L/R \) seconds/frame
  - \( a = t_{\text{prop}}/X \)
  - \( \nu \) meters/sec. speed of light in medium
  - \( d \) meters is diameter of system
  - \( 2e + 1 = 6.44 \)
CSMA-CD Application: Ethernet

- First Ethernet LAN standard used CSMA-CD
  - 1-persistent Carrier Sensing
  - $R = 10$ Mbps
  - $t_{prop} = 51.2$ microseconds
    - 512 bits = 64 byte slot
    - accommodates 2.5 km + 4 repeaters
  - Truncated Binary Exponential Backoff
    - After $n$th collision, select backoff from $\{0, 1, \ldots, 2^k - 1\}$, where $k = \min(n, 10)$
Throughput for Random Access MACs

- For small $a$: CSMA-CD has best throughput
- For larger $a$: Aloha & slotted Aloha better throughput
Carrier Sensing and Priority Transmission

- Certain applications require faster response than others, e.g. ACK messages
- Impose different interframe times
  - High priority traffic sense channel for time $\tau_1$
  - Low priority traffic sense channel for time $\tau_2 > \tau_1$
  - High priority traffic, if present, seizes channel first
- This priority mechanism is used in IEEE 802.11 wireless LAN
Chapter 6
Medium Access Control Protocols and Local Area Networks

Scheduling
Scheduling for Medium Access Control

- Schedule frame transmissions to avoid collision in shared medium
  - More efficient channel utilization
  - Less variability in delays
  - Can provide fairness to stations
  - Increased computational or procedural complexity

- Two main approaches
  - Reservation
  - Polling
Reservations Systems

- **Centralized systems**: A central controller accepts requests from stations and issues grants to transmit
  - Frequency Division Duplex (FDD): Separate frequency bands for uplink & downlink
  - Time-Division Duplex (TDD): Uplink & downlink time-share the same channel
- **Distributed systems**: Stations implement a decentralized algorithm to determine transmission order
Reservation Systems

Transmissions organized into cycles
Cycle: reservation interval + frame transmissions
Reservation interval has a minislot for each station to request reservations for frame transmissions
Reservation System Options

- Centralized or distributed system
  - *Centralized systems*: A central controller listens to reservation information, decides order of transmission, issues grants
  - *Distributed systems*: Each station determines its slot for transmission from the reservation information

- Single or Multiple Frames
  - *Single frame reservation*: Only one frame transmission can be reserved within a reservation cycle
  - *Multiple frame reservation*: More than one frame transmission can be reserved within a frame

- Channelized or Random Access Reservations
  - *Channelized (typically TDMA) reservation*: Reservation messages from different stations are multiplexed without any risk of collision
  - *Random access reservation*: Each station transmits its reservation message randomly until the message goes through
Example

- Initially stations 3 & 5 have reservations to transmit frames
- Station 8 becomes active and makes reservation
- Cycle now also includes frame transmissions from station 8
Efficiency of Reservation Systems

- Assume minislot duration = vX
- TDM single frame reservation scheme
  - If propagation delay is negligible, a single frame transmission requires \((1+v)X\) seconds
  - Link is fully loaded when all stations transmit, maximum efficiency is:
    \[
    \rho_{\text{max}} = \frac{MX}{Mv + MX} = \frac{1}{1 + v}
    \]
- TDM \(k\) frame reservation scheme
  - If \(k\) frame transmissions can be reserved with a reservation message and if there are \(M\) stations, as many as \(Mk\) frames can be transmitted in \(XM(k+v)\) seconds
  - Maximum efficiency is:
    \[
    \rho_{\text{max}} = \frac{MkX}{Mv + MkX} = \frac{1}{1 + \frac{v}{k}}
    \]
Random Access Reservation Systems

- *Large number of light traffic stations*
  - Dedicating a minislot to each station is inefficient

- Slotted ALOHA reservation scheme
  - Stations use slotted Aloha on reservation minislots
  - On average, each reservation takes at least $e$ minislot attempts
  - Effective time required for the reservation is $2.71vX$

\[
\rho_{\text{max}} = \frac{X}{X(1+ev)} = \frac{1}{1 + 2.71v}
\]
Example: GPRS

- General Packet Radio Service
  - Packet data service in GSM cellular radio
  - GPRS devices, e.g. cellphones or laptops, send packet data over radio and then to Internet
  - Slotted Aloha MAC used for reservations
  - Single & multi-slot reservations supported
Reservation Systems and Quality of Service

- Different applications; different requirements
  - Immediate transfer for ACK frames
  - Low-delay transfer & steady bandwidth for voice
  - High-bandwidth for Web transfers

- Reservation provide direct means for QoS
  - Stations makes requests per frame
  - Stations can request for persistent transmission access
  - Centralized controller issues grants
    - Preferred approach
    - Decentralized protocol allows stations to determine grants
      - Protocol must deal with error conditions when requests or grants are lost
Polling Systems

- *Centralized polling systems*: A central controller transmits polling messages to stations according to a certain order.
- *Distributed polling systems*: A permit for frame transmission is passed from station to station according to a certain order.
- A signaling procedure exists for setting up order.

![Diagram showing central controller and stations with arrows indicating polling messages]
Polling System Options

- **Service Limits**: How much is a station allowed to transmit per poll?
  - *Exhaustive*: until station’s data buffer is empty (including new frame arrivals)
  - *Gated*: all data in buffer when poll arrives
  - *Frame-Limited*: one frame per poll
  - *Time-Limited*: up to some maximum time

- **Priority mechanisms**
  - More bandwidth & lower delay for stations that appear multiple times in the polling list
  - Issue polls for stations with message of priority k or higher
Walk Time & Cycle Time

- Assume polling order is round robin
- Time is “wasted” polling stations
  - Time to prepare & send polling message
  - Time for station to respond
- *Walk time*: from when a station completes transmission to when next station begins transmission
- *Cycle time* is between consecutive polls of a station
- Overhead/cycle = total walk time/cycle time
Average Cycle Time

- Assume walk times all equal to $t'$
- Exhaustive Service: stations empty their buffers
- Cycle time $= Mt' + \text{time to empty } M \text{ station buffers}$
- \( \lambda/M \) be frame arrival rate at a station
- \( N_C \) average number of frames transmitted from a station
- Time to empty one station buffer:

\[
T_{\text{station}} = N_C X = \left( \frac{\lambda}{M} T_c \right) X = \frac{\rho T_c}{M}
\]

\[
\rho = \lambda X
\]

- Average Cycle Time:

\[
T_c = Mt' + MT_{\text{station}} = Mt' + \rho T_c \quad \Rightarrow \quad T_c = \frac{Mt'}{1 - \rho}
\]
Efficiency of Polling Systems

- **Exhaustive Service**
  - Cycle time increases as traffic increases, so delays become very large
  - Walk time per cycle becomes negligible compared to cycle time:
    \[
    \text{Efficiency} = \frac{MX - Mt'}{T_c} = \rho
    \]
    Can approach 100%

- **Limited Service**
  - Many applications cannot tolerate extremely long delays
  - Time or transmissions per station are limited
  - This limits the cycle time and hence delay
  - Efficiency of 100% is not possible

    \[
    \text{Efficiency} = \frac{MX}{MX + Mt'} = \frac{1}{1 + t'/X}
    \] Single frame per poll
Application: Token-Passing Rings

Free Token = Poll

Frame Delimiter is Token
Free = 01111110
Busy = 01111111

Listen mode

Input from ring → Delay → Output to ring

Ready station looks for free token
Flips bit to change free token to busy

Transmit mode

To device → Delay → From device

Ready station inserts its frames
Reinserts free token when done
Methods of Token Reinsertion

- **Ring latency**: number of bits that can be simultaneously in transit on ring
- **Multi-token operation**
  - Free token transmitted immediately after last bit of data frame
- **Single-token operation**
  - Free token inserted after last bit of the busy token is received back
  - Transmission time at least ring latency
  - If frame is longer than ring latency, equivalent to multi-token operation
- **Single-Frame operation**
  - Free token inserted after transmitting station has received last bit of its frame
  - Equivalent to attaching trailer equal to ring latency
Token Ring Throughput

- **Definition**
  - \(\tau'\): ring latency (time required for bit to circulate ring)
  - \(X\): maximum frame transmission time allowed per station

- **Multi-token operation**
  - Assume network is fully loaded, and all \(M\) stations transmit for \(X\) seconds upon the reception of a free token
  - This is a polling system with limited service time:

\[
\rho_{\text{max}} = \frac{MX}{\tau' + MX} = \frac{1}{1 + \frac{\tau'}{MX}} = \frac{1}{1 + \frac{a'}{M}}
\]

\[a' = \frac{\tau'}{X}\] is the normalized ring latency
Token Ring Throughput

- **Single-frame operation**
  - Effective frame transmission time is maximum of $X$ and $\tau'$, therefore

  $\rho_{\text{max}} = \frac{MX}{\tau' + M \max\{(X, \tau')\}} = \frac{1}{\max\{1, a'\} + a'/M}$

- **Single-token operation**
  - Effective frame transmission time is $X + \tau'$, therefore

  $\rho_{\text{max}} = \frac{MX}{\tau' + M(X + \tau')} = \frac{1}{1 + a'(1 + 1/M)}$
Token Reinsertion Efficiency Comparison

- $a << 1$, any token reinsertion strategy acceptable
- $a \approx 1$, single token reinsertion strategy acceptable
- $a > 1$, multitoken reinsertion strategy necessary
Application Examples

- Single-frame reinsertion
  - IEEE 802.5 Token Ring LAN @ 4 Mbps
- Single token reinsertion
  - IBM Token Ring @ 4 Mbps
- Multitoken reinsertion
  - IEEE 802.5 and IBM Ring LANs @ 16 Mbps
  - FDDI Ring @ 50 Mbps
- All of these LANs incorporate token priority mechanisms
Comparison of MAC approaches

- Aloha & Slotted Aloha
  - Simple & quick transfer at very low load
  - Accommodates large number of low-traffic bursty users
  - Highly variable delay at moderate loads
  - Efficiency does not depend on $a$

- CSMA-CD
  - Quick transfer and high efficiency for low delay-bandwidth product
  - Can accommodate large number of bursty users
  - Variable and unpredictable delay
Comparison of MAC approaches

- **Reservation**
  - On-demand transmission of bursty or steady streams
  - Accommodates large number of low-traffic users with slotted Aloha reservations
  - Can incorporate QoS
  - Handles large delay-bandwidth product via delayed grants

- **Polling**
  - Generalization of time-division multiplexing
  - Provides fairness through regular access opportunities
  - Can provide bounds on access delay
  - Performance deteriorates with large delay-bandwidth product
Chapter 6
Medium Access Control Protocols and Local Area Networks

Channelization
Why Channelization?

- Channelization
  - Semi-static bandwidth allocation of portion of shared medium to a given user
- Highly efficient for constant-bit rate traffic
- Preferred approach in
  - Cellular telephone networks
  - Terrestrial & satellite broadcast radio & TV
Why not Channelization?

- Inflexible in allocation of bandwidth to users with different requirements
- Inefficient for bursty traffic
- Does not scale well to large numbers of users
  - Average transfer delay increases with number of users \( M \)
- Dynamic MAC much better at handling bursty traffic
Channelization Approaches

- **Frequency Division Multiple Access (FDMA)**
  - Frequency band allocated to users
  - Broadcast radio & TV, analog cellular phone

- **Time Division Multiple Access (TDMA)**
  - Periodic time slots allocated to users
  - Telephone backbone, GSM digital cellular phone

- **Code Division Multiple Access (CDMA)**
  - Code allocated to users
  - Cellular phones, 3G cellular
Channelization: FDMA

- Divide channel into $M$ frequency bands
- Each station transmits and listens on assigned bands
- Each station transmits at most $R/M$ bps
- Good for stream traffic; Used in connection-oriented systems
- Inefficient for bursty traffic
Channelization: TDMA

- Dedicate 1 slot per station in transmission cycles
- Stations transmit data burst at full channel bandwidth

- Each station transmits at $R$ bps $1/M$ of the time
- Excellent for stream traffic; Used in connection-oriented systems
- Inefficient for bursty traffic due to unused dedicated slots
Guardbands

- **FDMA**
  - Frequency bands must be non-overlapping to prevent interference
  - Guardbands ensure separation; form of overhead

- **TDMA**
  - Stations must be synchronized to common clock
  - Time gaps between transmission bursts from different stations to prevent collisions; form of overhead
  - Must take into account propagation delays
Channelization: CDMA

- Code Division Multiple Access
  - Channels determined by a code used in modulation and demodulation
- Stations transmit over entire frequency band all of the time!
CDMA Spread Spectrum Signal

Transmitter from one user

- Binary information: \( R_1 \text{ bps} \)
- \( W_1 \text{ Hz} \)
- Unique user binary random sequence
- \( R >> R_1 \text{ bps} \)
- \( W >> W_1 \text{ Hz} \)

- Digital modulation

- User information mapped into: +1 or -1 for T sec.
- Multiply user information by pseudo-random binary pattern of G “chips” of +1’s and -1’s
- Resulting spread spectrum signal occupies G times more bandwidth: \( W = GW_1 \)
- Modulate the spread signal by sinusoid at appropriate \( f_c \)
CDMA Demodulation

- Recover spread spectrum signal
- Synchronize to and multiply spread signal by *same* pseudo-random binary pattern used at the transmitter
- In absence of other transmitters & noise, we should recover the original +1 or -1 of user information
- Other transmitters using different codes appear as residual noise
Pseudorandom pattern generator

- Feedback shift register with appropriate feedback taps can be used to generate pseudorandom sequence

\[ g(x) = x^3 + x^2 + 1 \]

The coefficients of a primitive generator polynomial determine the feedback taps

Sequence repeats from here onwards
Channelization in Code Space

- Each channel uses a different pseudorandom code
- Codes should have low cross-correlation
  - If they differ in approximately half the bits the correlation between codes is close to zero and the effect at the output of each other’s receiver is small
- As number of users increases, effect of other users on a given receiver increases as additive noise
- CDMA has gradual increase in BER due to noise as number of users is increased
- Interference between channels can be eliminated if codes are selected so they are orthogonal and if receivers and transmitters are synchronized
  - Shown in next example
Example: CDMA with 3 users

- Assume three users share the same medium.
- Users are synchronized and use different 4-bit orthogonal codes: 
  \{-1,-1,-1,-1\}, \{-1,+1,-1,+1\}, \{-1,-1,+1,+1\}, \{-1,+1,+1,-1\}, \{+1,-1,+1,-1\}.

Diagram:

- User 1: \{-1, -1, +1\}
- User 2: \{+1, -1, +1\}
- User 3: \{+1, +1, -1\}

Receiver

Shared Medium
Sum signal is input to receiver

Channel 1: 110 \rightarrow +1+1-1 \rightarrow (-1,-1,-1,-1), (-1,-1,-1,-1), (+1,+1,+1,+1)
Channel 2: 010 \rightarrow -1+1-1 \rightarrow (+1,-1,+1,-1), (-1,+1,-1,+1), (+1,-1,+1,-1)
Channel 3: 001 \rightarrow -1-1+1 \rightarrow (+1,+1,-1,-1), (+1,+1,-1,-1), (-1,-1,+1,+1)
Sum Signal: (+1,-1,-1,-3), (-1,+1,-3,-1), (+1,-1,+3,+1)
Example: Receiver for Station 2

- Each receiver takes sum signal and integrates by code sequence of desired transmitter
- Integrate over T seconds to smooth out noise
Decoding at Receiver 2

Sum Signal: (+1, -1, -1, -3), (-1, +1, -3, -1), (+1, -1, +3, +1)
Channel 2 Sequence: (-1, +1, -1, +1), (-1, +1, -1, +1), (-1, +1, -1, +1)
Correlator Output: (-1, -1, +1, -3), (+1, +1, +3, -1), (-1, -1, -3, +1)
Integrated Output: -4, +4, -4
Binary Output: 0, 1, 0

Diagram illustrating the processing steps as described above.
Walsh Functions

- Walsh functions are provide orthogonal code sequences by mapping 0 to -1 and 1 to +1
- Walsh matrices constructed recursively as follows:

$$W_{2n} = \begin{pmatrix} W_n & W_n \\ W_n & W_n \end{pmatrix}$$

$$W_1 = \begin{pmatrix} 0 \end{pmatrix}$$  $$W_2 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$$

$$W_4 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 \end{pmatrix}$$

$$W_8 = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 \end{pmatrix}$$
Channelization in Cellular Telephone Networks

- Cellular networks use frequency reuse
  - Band of frequencies reused in other cells that are sufficiently far that interference is not a problem
  - Cellular networks provide voice connections which is steady stream
- FDMA used in AMPS
- TDMA used in IS-54 and GSM
- CDMA used in IS-95
Advanced Mobile Phone System

- Advanced Mobile Phone System (AMPS)
  - First generation cellular telephone system in US
  - Analog voice channels of 30 kHz
  - Forward channels from base station to mobiles
  - Reverse channels from mobiles to base
- Frequency band 50 MHz wide in 800 MHz region allocated to two service providers: “A” and “B”
AMPS Spectral Efficiency

- 50 MHz @ 30kHz gives 832 2-way channels
- Each service provider has
  - 416 2-way channels
  - 21 channels used for call setup & control
  - 395 channels used for voice
- AMPS uses 7-cell frequency reuse pattern, so each cell has 395/7 voice channels

- AMPS spectrum efficiency: \#calls/cell/MHz
  - \((395.7)/(25 \text{ MHz}) = 2.26 \text{ calls/cell/MHz}\)
Interim Standard 54/136

- IS-54, and later IS-136, developed to meet demand for cellular phone service
- Digital methods to increase capacity
- A 30-kHz AMPS channel converted into several TDMA channels
  - 1 AMPS channel carries 48.6 kbps stream
  - Stream arranged in 6-slot 40 ms cycles
  - 1 slot = 324 bits → 8.1 kbps per slot
  - 1 full-rate channel: 2 slots to carry 1 voice signal
- 1 AMPS channel carries 3 voice calls
- 30 kHz spacing also used in 1.9 GHz PCS band
IS-54 TDMA frame structure

- 416 AMPS channels x 3 = 1248 digital channels
- Assume 21 channels for calls setup and control
- IS-54 spectrum efficiency: \#calls/cell/MHz
  - \((1227/7)/(25 \text{ MHz}) = 3 \text{ calls/cell/MHz}\)
Global System for Mobile Communications (GSM)

- European digital cellular telephone system
- 890-915 MHz & 935-960 MHz band
- PCS: 1800 MHz (Europe), 1900 MHz (N.Am.)
- Hybrid TDMA/FDMA
  - Carrier signals 200 kHz apart
  - 25 MHz give 124 one-way carriers
Each carrier signal carries traffic and control channels
1 full rate traffic channel = 1 slot in every traffic frame
24 slots x 114 bits/slot / 120 ms = 22.8 kbps
GSM Spectrum Efficiency

- Error correction coding used in 22.8 kbps to carry 13 kbps digital voice signal
- Frequency reuse of 3 or 4 possible
- 124 carriers x 8 = 992 traffic channels
- Spectrum efficiency for GSM:
  - \( \frac{992}{3} \)/50MHz = 6.61 calls/cell/MHz
Interim Standard 95 (IS-95)

- CDMA digital cellular telephone system
- Operates in AMPS & PCS bands
- 1 signal occupies 1.23 MHz
  - 41 AMPS signals
- All base stations are synchronized to a common clock
  - Global Positioning System accuracy to 1 μsec
- Forward channels use orthogonal spreading
- Reverse channels use non-orthogonal spreading
Base-to-Mobile Channels

- Basic user information rate is 9.6 kbps
- Doubled after error correction coding
- Converted to ±1s
- Multiplied by 19.2 ksym/sec stream derived from 42-bit register long-code sequence generator which depends on electronic serial number
Each symbol multiplied by 64-bit chip Walsh orthogonal sequence (19200 x 64 = 1.2288 Msym/sec)

Each base station uses the same 15-bit register short sequence to spread signal prior to transmission

Base station synchronizes all its transmissions
Pilot Tone & Synchronization

- All 0’s Walsh sequence reserved to generate pilot tone
- Short code sequences transmitted to all receivers
- Receivers can then recover user information using Walsh orthogonal sequence
- Different base stations use different phase of same short sequence
- Mobiles compare signal strengths of pilots from different base stations to decide when to initiate handoff
Mobile-to-Base Channels

- 9.6 kbps user information coded and spread to 307.2 kbps
- Spread by 4 by multiplying by long code sequence
- Different mobiles use different phase of long code sequence
- Multiplied by short code sequence
- Transmitted to Base
IS-95 Spectrum Efficiency

- Spread spectrum reduces interference
  - Signals arriving at a base station from within or from outside its cell are uncorrelated because mobiles have different long code sequences
  - Signals arriving at mobiles from different base stations are uncorrelated because they use different phases of the short code sequence
- *Enables reuse factor of 1*
- Goodman [1997] estimates spectrum efficiency for IS-95 is:
  - between 12 & 45 call/cell/MHz
- *Much higher spectrum efficiency than IS-54 & GSM*
Chapter 6
Medium Access Control Protocols and Local Area Networks

Delay Performance
Statistical Multiplexing & Random Access

- Multiplexing concentrates bursty traffic onto a shared line
- Packets are encapsulated in frames and queued in a buffer prior to transmission
- Central control allows variety of service disciplines
- MAC allows sharing of a broadcast medium
- Packets are encapsulated in frames and queued at station prior to transmission
- Decentralized control “wastes” bandwidth to allow sharing

M/G/1 Queueing Model for Statistical Multiplexer

- **Arrival Model**
  - Independent frame interarrival times:
  - Average $1/\lambda$
  - Exponential distribution
  - “Poisson Arrivals”

- **Frame Length Model**
  - Independent frame transmission times $X$
  - Average $E[X] = 1/\mu$
  - General distribution
  - Constant, exponential, …

- **Infinite Buffer**
  - No Blocking

- **Load** $\rho = \lambda/\mu$
  - Stability Condition: $\rho < 1$

We will use M/G/1 model as baseline for MAC performance
Total Delay = Waiting Time + Service Time

Average Waiting Time:

\[ E[W] = \frac{\rho}{2(1-\rho)} \left(1 + \frac{\sigma_X^2}{E[X]^2}\right)E[X] \]

Average Total Delay:

\[ E[T] = E[W] + E[X] \]

Example: M/D/1

\[ E[W] = \frac{\rho}{2(1-\rho)} E[X] \]
M/G/1 Vacation Model

- In M/G/1 model, a frame arriving to an empty multiplexer begins transmission immediately.
- In many MACs, there is a delay before transmission can begin.
- **M/G/1 Vacation Model**: when system empties, server goes away on vacation for random time $V$

\[
E[W] = \frac{\rho}{2(1-\rho)} \left( 1 + \frac{\sigma_X^2}{E[X]^2} \right) E[X] + \frac{E[V^2]}{2E[V]}
\]

Extra delay term
Performance of FDMA & CDMA
Channelization Bursty Traffic

- M stations do not interact
- Poisson arrivals $\lambda/M$ fr/sec
- Constant frame length L bits
- Transmission time at full rate
  - $X=L/R$
- Station bit rate is $R/M$
  - Neglect guardbands
- Transmission time from station
  - $L/(R/M)=M(L/R)=MX$
  - M times longer
- Load at one station:
  - $\rho=(\lambda/M)MX=\lambda X$
Transfer Delay for FDMA and CDMA

- Time-slotted transmission from each station
- When station becomes empty, transmitter goes on vacation for 1 time slot of constant duration $V = MX$

\[
E[W_{FDMA}] = \frac{\rho}{2(1 - \rho)} MX + \frac{V}{2} = \frac{\rho}{2(1 - \rho)} MX + \frac{MX}{2}
\]

- Average Total Transfer Delay is:

\[
E[T_{FDMA}] = E[W_{FDMA}] + MX = \frac{\rho}{2(1 - \rho)} MX + \frac{MX}{2} + MX
\]

- The delay increases in proportion with $M$, the number of stations
- Allocated bandwidth to a given station is wasted when other stations have data to send
Transfer Delay of TDMA & CDMA

FDMA
Our frame arrives and finds two frames in queue
First frame transmitted
Second frame transmitted
Our frame finishes transmission

TDMA
Our frame arrives and finds two frames in queue
First frame transmitted
Second frame transmitted
Last TDMA frame finishes sooner
Our frame finishes transmission

FDMA & TDMA have same waiting time
Transfer Delay for TDMA

- Time-slotted transmission from each station
- Same waiting time as FDMA

\[ E[W_{TDMA}] = \frac{\rho}{2(1-\rho)} MX + \frac{MX}{2} \]

- Frame service time is \( X \)
- Average Total Transfer Delay is:

\[ E[T_{TDMA}] = \frac{\rho}{2(1-\rho)} MX + \frac{MX}{2} + X \]

- Better than FDMA & CDMA
- Total Delay still grows proportional to \( M \)
TDMA Average Transfer Delay

\[ E[T/X] \]

\[ \rho \]

\( M^1 \)
\( M^2 \)
\( M^4 \)
\( M^8 \)
\( M^16 \)
Assume “exhaustive service” where a station keeps token until its buffer is empty.

Average cycle time is:

\[ T_c = \frac{\tau'}{1 - \rho} \]

where \( \tau' \) is total walk time required to poll all stations without transmissions.
Polling Systems

- The transfer delay has three components:
  - residual cycle time (approximate by $\frac{T_c}{2}$)
  - mean waiting time (approximate by M/G/1)
  - packet transmission time
  - propagation time from source to destination ($\tau_{\text{average}}$)
- We obtain the following approximation:

  \[
  T = E[X] = \tau_{\text{average}} + \frac{\tau'}{2(1 - \rho)} + \frac{\rho}{2(1 - \rho)} E[X]
  \]
- A precise analysis of the this model gives:

  \[
  T = E[X] = \tau_{\text{average}} + \frac{\tau'(1 - \rho/M)}{2(1 - \rho)} + \frac{\rho}{2(1 - \rho)} E[X]
  \]
Example: Transfer Delay in Polling System

- Exhaustive service
- For $\alpha' \ll 1$, essentially M/D/1 performance
- Much better than channelization
- For larger $\alpha'$, delay proportional to $\alpha'$
- Mild, indirect dependence on $M$, since $\alpha' = Mt'/X$
Example: Transfer Delay in Ring LAN

- Exhaustive service
- M=32 stations
- Much better than channelization
- For larger $a'$, delay proportional to $a'$
Mean Waiting Time Token Ring

$M = 32$

Unlimited service/token

$M = 32$

1 packet/token

Multitoken ring
Mean Waiting Time Token Ring

$M = 32$

Unlimited service/token

$M = 32$

1 packet/token

Single token ring

Ring latency limits throughput severely
Chapter 6
Medium Access Control Protocols and Local Area Networks

Part II: Local Area Networks
Overview of LANs
Ethernet
Token Ring and FDDI
802.11 Wireless LAN
LAN Bridges
Chapter 6
Medium Access Control Protocols and Local Area Networks

Overview of LANs
What is a LAN?

Local area means:

- Private ownership
  - freedom from regulatory constraints of WANs
- Short distance (~1km) between computers
  - low cost
  - very high-speed, relatively error-free communication
  - complex error control unnecessary
- Machines are constantly moved
  - Keeping track of location of computers a chore
  - Simply give each machine a unique address
  - *Broadcast* all messages to all machines in the LAN
- Need a *medium access control protocol*
Typical LAN Structure

- Transmission Medium
- Network Interface Card (NIC)
- Unique MAC "physical" address
Medium Access Control Sublayer

- In IEEE 802.1, Data Link Layer divided into:
  1. Medium Access Control Sublayer
     - Coordinate access to medium
     - Connectionless frame transfer service
     - Machines identified by MAC/physical address
     - Broadcast frames with MAC addresses
  2. Logical Link Control Sublayer
     - Between Network layer & MAC sublayer
MAC Sub-layer

Logical Link Control Layer

- IEEE 802.2: LLC enhances service provided by MAC

Unreliable Datagram Service

Reliable frame service
Logical Link Control Services

- **Type 1:** Unacknowledged connectionless service
  - Unnumbered frame mode of HDLC
- **Type 2:** Reliable connection-oriented service
  - Asynchronous balanced mode of HDLC
- **Type 3:** Acknowledged connectionless service

- **Additional addressing**
  - A workstation has a single MAC physical address
  - Can handle several logical connections, distinguished by their SAP (service access points).
LLC PDU Structure

I/G = Individual or group address
C/R = Command or response frame

Examples of SAP Addresses:
06  IP packet
E0  Novell IPX
FE  OSI packet
AA  SubNetwork Access protocol (SNAP)
Encapsulation of MAC frames

Chapter 6
Medium Access Control
Protocols and Local Area Networks

Ethernet
A bit of history...

- 1970  ALOHAnet radio network deployed in Hawaiian islands
- 1973  Metcalf and Boggs invent Ethernet, random access in wired net
- 1979  DIX Ethernet II Standard
- 1985  IEEE 802.3 LAN Standard (10 Mbps)
- 1995  Fast Ethernet (100 Mbps)
- 1998  Gigabit Ethernet
- 2002  10 Gigabit Ethernet
- Ethernet is the dominant LAN standard

Metcalf’s Sketch
IEEE 802.3 MAC: Ethernet

MAC Protocol:
- CSMA/CD
- *Slot Time* is the critical system parameter
  - upper bound on time to detect collision
  - upper bound on time to acquire channel
  - upper bound on length of frame segment generated by collision
  - quantum for retransmission scheduling
  - max{round-trip propagation, MAC jam time}
- Truncated binary exponential backoff
  - for retransmission n: $0 < r < 2^k$, where $k = \min(n, 10)$
  - Give up after 16 retransmissions
IEEE 802.3 Original Parameters

- Transmission Rate: 10 Mbps
- Min Frame: 512 bits = 64 bytes
- Slot time: 512 bits/10 Mbps = 51.2 μsec
  - 51.2 μsec x 2x10^5 km/sec = 10.24 km, 1 way
  - 5.12 km round trip distance
- Max Length: 2500 meters + 4 repeaters

Each x10 increase in bit rate, must be accompanied by x10 decrease in distance
• Every frame transmission begins “from scratch”
• Preamble helps receivers synchronize their clocks to transmitter clock
• 7 bytes of 10101010 generate a square wave
• Start frame byte changes to 10101011
• Receivers look for change in 10 pattern
IEEE 802.3 MAC Frame

- Destination address
  - single address
  - group address
  - broadcast = 111...111

- Addresses
  - local or global

- Global addresses
  - first 24 bits assigned to manufacturer;
  - next 24 bits assigned by manufacturer
  - Cisco 00-00-0C
  - 3COM 02-60-8C
IEEE 802.3 MAC Frame

- **Length**: # bytes in information field
  - Max frame 1518 bytes, excluding preamble & SD
  - Max information 1500 bytes: 05DC
- **Pad**: ensures min frame of 64 bytes
- **FCS**: CCITT-32 CRC, covers addresses, length, information, pad fields
  - NIC discards frames with improper lengths or failed CRC
DIX Ethernet II Frame Structure

- DIX: Digital, Intel, Xerox joint Ethernet specification
- Type Field: to identify protocol of PDU in information field, e.g. IP, ARP
- Framing: How does receiver know frame length?
  - physical layer signal, byte count, FCS
SubNetwork Address Protocol (SNAP)

- IEEE standards assume LLC always used
- Higher layer protocols developed for DIX expect type field
- DSAP, SSAP = AA, AA indicate SNAP PDU;
- 03 = Type 1 (connectionless) service
- SNAP used to encapsulate Ethernet II frames
IEEE 802.3 Physical Layer

Thick Coax: Stiff, hard to work with

T connectors flaky
**Ethernet Hubs & Switches**

(a) Single collision domain

- Twisted Pair
- Cheap
- Easy to work with
- Reliable
- Star-topology CSMA-CD

(b) High-Speed backplane or interconnection fabric

- Twisted Pair
- Cheap
- Bridging increases scalability
- Separate collision domains
- Full duplex operation
Ethernet Scalability

- CSMA-CD maximum throughput depends on normalized delay-bandwidth product $a = t_{prop}/X$
- $x10$ increase in bit rate = $x10$ decrease in $X$
- To keep $a$ constant need to either: decrease $t_{prop}$ (distance) by $x10$; or increase frame length $x10$
Fast Ethernet

- Frame structure preserved
- CSMA-CD protocol officially abandoned
- LAN PHY for local network applications
- WAN PHY for wide area interconnection using SONET OC-192c
- Extensive deployment in metro networks anticipated
Typical Ethernet Deployment
Chapter 6
Medium Access Control Protocols and Local Area Networks

Token Ring and FDDI
IEEE 802.5 Ring LAN

- Unidirectional ring network
- 4 Mbps and 16 Mbps on twisted pair
  - Differential Manchester line coding
- Token passing protocol provides access
  - Fairness
  - Access priorities
  - Breaks in ring bring entire network down
- Reliability by using star topology
Star Topology Ring LAN

- Stations connected in star fashion to wiring closet
  - Use existing telephone wiring
- Ring implemented inside equipment box
- Relays can bypass failed links or stations
Token Frame Format

Length limited by allowable token holding time

**FCS**

CCITT-32 CRC

**Frame status**

| A | C | xx | A | C | xx |

A = address-recognized bit
xx = undefined
C = frame-copied bit
Other Ring Functions

- **Priority Operation**
  - PPP provides 8 levels of priority
  - Stations wait for token of equal or lower priority
  - Use RRR bits to “bid up” priority of next token

- **Ring Maintenance**
  - Sending station must remove its frames
  - Error conditions
    - Orphan frames, disappeared token, frame corruption
  - *Active monitor station* responsible for removing orphans
Ring Latency & Ring Reinsertion

- M stations
- b bit delay at each station
  - $B=2.5$ bits (using Manchester coding)
- Ring Latency:
  - $\tau' = \frac{d}{\nu} + \frac{Mb}{R}$ seconds
  - $\tau'R = \frac{dR}{\nu} + Mb$ bits
- Example
  - Case 1: $R=4$ Mbps, $M=20$, 100 meter separation
    - Latency = $20 \times 100 \times 4 \times 10^6/(2 \times 10^8)+20 \times 2.5=90$ bits
  - Case 2: $R=16$ Mbps, $M=80$
    - Latency = 840 bits
(a) Low Latency (90 bit) Ring

\[
\begin{align*}
& t = 0, \text{ A begins frame} \\
& t = 90, \text{ return of first bit} \\
& t = 210, \text{ return of header} \\
& t = 400, \text{ last bit enters ring, reinsert token}
\end{align*}
\]

(b) High Latency (840 bit) Ring

\[
\begin{align*}
& t = 0, \text{ A begins frame} \\
& t = 400, \text{ transmit last bit} \\
& t = 840, \text{ arrival first frame bit} \\
& t = 960, \text{ reinsert token}
\end{align*}
\]
Fiber Distributed Data Interface (FDDI)

- Token ring protocol for LAN/MAN
- Counter-rotating dual ring topology
- 100 Mbps on optical fiber
- Up to 200 km diameter, up to 500 stations
- Station has 10-bit “elastic” buffer to absorb timing differences between input & output
- Max frame 40,000 bits
- 500 stations @ 200 km gives ring latency of 105,000 bits
- FDDI has option to operate in multitoken mode
Dual ring becomes a single ring
# FDDI Frame Format

## Data Frame Format

<table>
<thead>

<td>1</td>
<td>6</td>
<td>6</td>
<td></td>
<td></td>
<td>4</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

**Preamble**

Frame control: CLFFZZZZ

- **C** = synch/asynch
- **L** = address length (16 or 48 bits)
- **FF** = LLC/MAC control/reserved frame type

CLFFZZZZ = 10000000 or 11000000 denotes token frame

## Token Frame Format

<table>
<thead>

</thead>
<tbody>
<tr>
<td>8</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
Timed Token Operation

- Two traffic types
  - Synchronous
  - Asynchronous
- All stations in FDDI ring agree on target token rotation time (TTRT)
- Station i has $S_i$, max time to send synch traffic
- Token rotation time is less than 2*TTRT if
  - $S_1 + S_2 + \ldots + S_{M-1} + S_M < 2 \times \text{TTRT}$
  - FDDI guarantees access delay to synch traffic

Station Operation

- Maintain Token Rotation Timer (TRT): time since station last received token
- When token arrives, find Token Holding Time
  - $THT = \text{TTRT} - \text{TRT}$
  - $THT > 0$, station can send all synchronous traffic up to $S_i + THT - S_i$ data traffic
  - $THT < 0$, station can only send synchronous traffic up to $S_i$
- As ring activity increases, TRT increases and asynch traffic throttled down
Chapter 6
Medium Access Control Protocols and Local Area Networks

802.11 Wireless LAN
Wireless Data Communications

- Wireless communications compelling
  - Easy, low-cost deployment
  - Mobility & roaming: Access information anywhere
  - Supports personal devices
    - PDAs, laptops, data-cell-phones
  - Supports communicating devices
    - Cameras, location devices, wireless identification
- Signal strength varies in space & time
- Signal can be captured by snoopers
- Spectrum is limited & usually regulated
Ad Hoc Communications

- Temporary association of group of stations
  - Within range of each other
  - Need to exchange information
  - E.g. Presentation in meeting, or distributed computer game, or both

IEEE 802.11 Wireless LAN

- Stimulated by availability of *unlicensed spectrum*
  - U.S. Industrial, Scientific, Medical (ISM) bands
  - 902-928 MHz, 2.400-2.4835 GHz, 5.725-5.850 GHz
- Targeted wireless LANs @ 20 Mbps
- MAC for high speed wireless LAN
- Ad Hoc & Infrastructure networks
- Variety of physical layers
802.11 Definitions

- **Basic Service Set (BSS)**
  - Group of stations that coordinate their access using a given instance of MAC
  - Located in a *Basic Service Area* (BSA)
  - Stations in BSS can communicate with each other
  - Distinct collocated BSS’s can coexist

- **Extended Service Set (ESS)**
  - Multiple BSSs interconnected by *Distribution System* (DS)
  - Each BSS is like a cell and stations in BSS communicate with an *Access Point* (AP)
  - *Portals* attached to DS provide access to Internet
Infrastructure Network

Server

Portal

Gateway to the Internet

Distribution System

Portal

AP1

BSS A

A2

B1

B2

AP2

BSS B
Distribution Services

- Stations within BSS can communicate directly with each other
- DS provides *distribution services*:
  - Transfer MAC SDUs between APs in ESS
  - Transfer MSDUs between portals & BSSs in ESS
  - Transfer MSDUs between stations in same BSS
    - Multicast, broadcast, or stations’s preference
- ESS looks like single BSS to LLC layer
Infrastructure Services

- Select AP and establish *association* with AP
  - Then can send/receive frames via AP & DS
- *Reassociation service* to move from one AP to another AP
- *Dissociation service* to terminate association
- *Authentication service* to establish identity of other stations
- *Privacy service* to keep contents secret
IEEE 802.11 MAC

- MAC sublayer responsibilities
  - Channel access
  - PDU addressing, formatting, error checking
  - Fragmentation & reassembly of MAC SDUs
- MAC security service options
  - Authentication & privacy
- MAC management services
  - Roaming within ESS
  - Power management
MAC Services

- Contention Service: Best effort
- Contention-Free Service: time-bounded transfer
- MAC can alternate between Contention Periods (CPs) & Contention-Free Periods (CFPs)

Contention-free service

Point coordination function

Distribution coordination function (CSMA-CA)

Physical

Contention service

MSDUs

MSDUs

MAC
Distributed Coordination Function (DCF)

- DCF provides basic access service
  - Asynchronous best-effort data transfer
  - All stations contend for access to medium

- CSMA-CA
  - Ready stations wait for completion of transmission
  - All stations must wait *Interframe Space (IFS)*
Priorities through Interframe Spacing

- High-Priority frames wait Short IFS (SIFS)
  - Typically to complete exchange in progress
  - ACKs, CTS, data frames of segmented MSDU, etc.
- PCF IFS (PIFS) to initiate Contention-Free Periods
- DCF IFS (DIFS) to transmit data & MPDUs
Contention & Backoff Behavior

- If channel is still idle after DIFS period, ready station can transmit an *initial* MPDU
- If channel becomes busy before DIFS, then station must schedule *backoff* time for reattempt
  - Backoff period is integer # of *idle contention time slots*
  - Waiting station monitors medium & decrements backoff timer each time an idle contention slot transpires
  - Station can contend when backoff timer expires
- A station that completes a frame transmission is not allowed to transmit immediately
  - Must first perform a backoff procedure
A requests to send

B announces A ok to send

A sends

C remains quiet

B sends ACK
Carrier Sensing in 802.11

- **Physical Carrier Sensing**
  - Analyze all detected frames
  - Monitor relative signal strength from other sources

- **Virtual Carrier Sensing** at MAC sublayer
  - Source stations informs other stations of transmission time (in \(\mu\text{sec}\)) for an MPDU
  - Carried in *Duration* field of RTS & CTS
  - Stations adjust *Network Allocation Vector* to indicate when channel will become idle

- Channel busy if either sensing is busy
Transmission of MPDU without RTS/CTS

- **DIFS**: Data
  
  - **Source**: Data transmission
  
  - **Destination**: Acknowledgment (ACK)
  
- **SIFS**: Source-Intermediate Frame Separation

- **NAV**: Network Allocation Vector
  
  - **Other**: NAV access

- **Defer Access**: Wait for retransmission time

- **Wait for Reattempt Time**: After DIFS, NAV access is deferred.
Transmission of MPDU with RTS/CTS

- DIFS
- RTS
- SIFS
- CTS
- SIFS
- Data
- SIFS
- Ack
- NAV (RTS)
- NAV (CTS)
- NAV (Data)
- Defer access

Source

Destination

Other
Collisions, Losses & Errors

● Collision Avoidance
  ● When station senses channel busy, it waits until channel becomes idle for DIFS period & then begins random backoff time (in units of idle slots)
  ● Station transmits frame when backoff timer expires
  ● If collision occurs, recompute backoff over interval that is twice as long

● Receiving stations of error-free frames send ACK
  ● Sending station interprets non-arrival of ACK as loss
  ● Executes backoff and then retransmits
  ● Receiving stations use sequence numbers to identify duplicate frames
Point Coordination Function

- PCF provides connection-oriented, contention-free service through polling
- *Point coordinator (PC)* in AP performs PCF
- Polling table up to implementor
- CFP repetition interval
  - Determines frequency with which CFP occurs
  - Initiated by *beacon frame* transmitted by PC in AP
  - Contains CFP and CP
  - During CFP stations may only transmit to respond to a poll from PC or to send ACK
PCF Frame Transfer

D1, D2 = frame sent by point coordinator
U1, U2 = frame sent by polled station
TBTT = target beacon transmission time
B = beacon frame
Frame Types

- **Management frames**
  - Station association & disassociation with AP
  - Timing & synchronization
  - Authentication & deauthentication

- **Control frames**
  - Handshaking
  - ACKs during data transfer

- **Data frames**
  - Data transfer
MAC Header: 30 bytes
Frame Body: 0-2312 bytes
CRC: CCITT-32 4 bytes CRC over MAC header & frame body
Frame Control (1)

- Protocol version = 0
- Type: Management (00), Control (01), Data (10)
- Subtype within frame type
- Type=00, subtype=association; Type=01, subtype=ACK
- MoreFrag=1 if another fragment of MSDU to follow
### Frame Control (2)

To DS = 1 if frame goes to DS; From DS = 1 if frame exiting DS
Frame Control (3)

- Retry = 1 if mgmt/control frame is a retransmission
- Power Management used to put station in/out of sleep mode
- More Data = 1 to tell station in power-save mode more data buffered for it at AP
- WEP = 1 if frame body encrypted
802.11 designed to
- Support LLC
- Operate over many physical layers

Chapter 6
Medium Access Control Protocols and Local Area Networks

LAN Bridges
Hubs, Bridges & Routers

- **Hub**: Active central element in a star topology
  - Twisted Pair: inexpensive, easy to install
  - Simple repeater in Ethernet LANs
  - “Intelligent hub”: fault isolation, net configuration, statistics
- Requirements that arise:

User community grows, need to interconnect hubs
Hubs are for different types of LANs
Hubs, Bridges & Routers

- Interconnecting Hubs
  - Repeater: Signal regeneration
    - All traffic appears in both LANs
  - Bridge: MAC address filtering
    - Local traffic stays in own LAN
  - Routers: Internet routing
    - All traffic stays in own LAN

Higher Scalability
Operation at data link level implies capability to work with multiple network layers

However, must deal with

- Difference in MAC formats
- Difference in data rates; buffering; timers
- Difference in maximum frame length
Bridges of Same Type

- Common case involves LANs of same type
- Bridging is done at MAC level
Transparent Bridges

- Interconnection of IEEE LANs with complete transparency
- Use table lookup, and
  - discard frame, if source & destination in same LAN
  - forward frame, if source & destination in different LAN
  - use flooding, if destination unknown
- Use backward learning to build table
  - observe source address of arriving LANs
  - handle topology changes by removing old entries
**S4 → S3**

- **LAN1**
  - **S1**: Port 1 (Address: S1, Port: 1)
  - **S2**: Port 2 (Address: S3, Port: 2)

- **LAN2**
  - **B1**: Port 2 (Address: S4, Port: 2)
  - **S3**: Port 1 (Address: S4, Port: 2)

- **LAN3**
  - **S4**: Port 1 (Address: S3, Port: 1)
  - **B2**: Port 2 (Address: S4, Port: 2)

</tbody>
</table>
Adaptive Learning

- In a static network, tables eventually store all addresses & learning stops
- In practice, stations are added & moved all the time
  - Introduce timer (minutes) to age each entry & force it to be relearned periodically
  - If frame arrives on port that differs from frame address & port in table, update immediately
Avoiding Loops
Spanning Tree Algorithm

1. Select a *root bridge* among all the bridges.
   - root bridge = the lowest bridge ID.

2. Determine the *root port* for each bridge except the root bridge
   - root port = port with the least-cost path to the root bridge

3. Select a *designated bridge* for each LAN
   - designated bridge = bridge has least-cost path from the LAN to the root bridge.
   - designated port connects the LAN and the designated bridge

4. All root ports and all designated ports are placed into a “forwarding” state. These are the only ports that are allowed to forward frames. The other ports are placed into a “blocking” state.
Bridge 1 selected as root bridge
Root port selected for every bridge except root port
Select designated bridge for each LAN
All root ports & designated ports put in forwarding state
Source Routing Bridges

- To interconnect IEEE 802.5 token rings
- Each source station determines route to destination
- Routing information inserted in frame
Route Discovery

- To discover route to a destination each station broadcasts a *single-route broadcast frame*
- Frame visits every LAN once & eventually reaches destination
- Destination sends *all-routes broadcast frame* which generates all routes back to source
- Source collects routes & picks best
Detailed Route Discovery

- Bridges must be configured to form a spanning tree
- Source sends *single-route frame* without route designator field
- Bridges in first LAN add incoming LAN #, its bridge #, outgoing LAN # into frame & forwards frame
- Each subsequent bridge attaches its bridge # and outgoing LAN #
- Eventually, *one* single-route frame arrives at destination

- When destination receives single-route broadcast frame it responds with *all-routes broadcast frame* with no route designator field
- Bridge at first hop inserts incoming LAN #, its bridge #, and outgoing LAN # and forwards to outgoing LAN
- Subsequent bridges insert their bridge # and outgoing LAN # and forward
- Before forwarding bridge checks to see if outgoing LAN already in designator field
- Source eventually receives all routes to destination station

Bridge only forwards frames to outgoing ports associated with same VLAN
Tagged VLANs

- More flexible than Port-based VLANs
- Insert VLAN tag after source MAC address in each frame
  - VLAN protocol ID + tag
- VLAN-aware bridge forwards frames to outgoing ports according to VLAN ID
- VLAN ID can be associated with a port statically through configuration or dynamically through bridge learning
- IEEE 802.1q
